## Nicht-technische Zusammenfassung

Ausgründungen aus Hochschulen, sogenannte akademische Spin-Offs, haben in den letzten Jahren große Beachtung in der Innovationspolitik gefunden. In ganz Europa wurden Programme entwickelt, die unternehmerische Tätigkeiten von Akademikern fördern sollen. Aufgrund hoher Innovationsaktivitäten von akademischen Spin-Offs verspricht sich die Politik eine Stärkung der regionalen und nationalen Innovationsfähigkeit, was die Wettbewerbsfähigkeit erhöhen soll und damit nicht zuletzt für wirtschaftliches Wachstum sorgt.

Entgegen der weit verbreiteten Ansicht, dass akademische Spin-Offs direkt aus der Hochschule heraus gegründet werden, findet die Gründung der meisten Spin-Offs erst mehrere Jahre nach dem Verlassen der wissenschaftlichen Einrichtung statt. Eine Umfrage unter rund 20.000 neugegründeten Unternehmen im Jahre 2001, die auch die Datengrundlage dieser Arbeit ist, konnte zeigen, dass 50 Prozent aller deutschen Spin-Offs erst mehr als 4 Jahre nach dem Ausscheiden aus der Wissenschaft gegründet werden. Trotz dieser zeitlichen Verzögerung tragen diese Spin-Offs wesentlich zum Wissenstransfer bei. Diese Tatsache ist zwar nicht überraschend, aber recht neu, da die Möglichkeit einer „späten“ Gründung in der Literatur zwar bekannt ist, jedoch meist ignoriert wird.

Die vorliegende Arbeit untersucht, ob Spin-Offs, von denen eine höhere Intensität des Wissenstransfers angenommen wird, schneller gegründet werden und inwiefern eine Ausgründung komplementäre Fähigkeiten des Gründers erfordert. Die Ergebnisse einer Verweildaueranalyse zeigen, dass Spin-Offs mit einer höheren Wissenstransferintensität zeitlich näher an der Wissenschaft gegründet werden. Des Weiteren ist die Zeitspanne zwischen Wissenschaft und Gründung für jene Spin-Offs geringer, die in Teams gegründet werden oder deren Gründer nicht nur einer wissenschaftlichen Fachrichtung angehören. Dies bestärkt die These, dass für eine Ausgründung ein breites Spektrum an Fähigkeiten notwendig ist, die zueinander in komplementären Beziehungen stehen.

## Executive Summary

The creation of academic spin-offs has received great attention in innovation policy for the last couple of years. Throughout Europe policy programmes have been introduced to stimulate entrepreneurial activities of academic persons. Academic spin-offs are assigned to be highly innovative, and thus help to strengthen a regions or even a countries innovative ability, improve competitiveness and finally foster economic growth.

The prevalent view is that spin-offs are mostly established directly after leaving the academic institution. However a survey of around 20.000 newly-founded firms carried out in Germany in 2001, which is also the data base for the following paper, revealed that 50 percent of all German academic spin-offs founded between 1996 and 2001 were established 4 years or more after the founder left his academic institution. Despite this time-lag all spin-offs contributed to technology and knowledge transfer. The contribution could be inferred by the method academic spin-offs were identified.

This fact is not surprising, but rather new as the possibility of "late" founding was known but mostly ignored in the spin-off literature.

This paper focuses on the contribution of the existence of complementarities in skills and the intensity of technology and knowledge transfer, to the time which elapses after the founder has left the academic institution.

The results of a duration analysis made in this paper suggest that spin-offs with a higher intensity of knowledge transfer are established closer to the time directly after leaving university. Furthermore, spin-offs which are founded in teams have significantly shorter time-lags than those established by a single founder. Additionally, foundation is accelerated if the founder(s) studied certain combinations of academic subjects rather than a single subject. This supports the presumption that in order to establish a firm a broad spectrum of complementary skills is necessary which can either be obtained by market and business experience of a single founder or by forming a team.

# University Spin-Off's Transfer Speed - Analyzing the Time from Leaving University to Venture

Kathrin Müller \*

June, 2008

## Abstract

For academic spin-offs I analyze the length of time between the founder's leaving of academia and the establishment of his firm. Technology transfer can take place even years after leaving the mother institution. A duration analysis reveals that a longer time-lag is caused by the necessity of assembling complementary skills, either by acquisition by a single founder or by searching for suitable team members. Furthermore, new ventures are established earlier if the intensity of technology transfer is high, the founders have access to university infrastructure, or received informal support by former colleagues.

# 1 Introduction

Technology transfer, i.e. the commercialization of public research results, can take place through many different channels. One important channel is the formation of new firms which are based on research, knowledge or skills created in a public research institution<sup>1</sup>. Bercovitz and Feldmann (2006) identify the establishment of those firms, known as academic spin-offs, as one of the core mechanisms of university technology transfer besides sponsored research, licensing out of R&D results and hiring of students or researchers. Technology transfer can also proceed through other channels such as adoption of tacit knowledge or publications.

For licensing, Jensen and Thursby (2001) found that inventions are so "embryonic" at the time of licensing that it is not known whether the invention will become successfully commercialized. Most inventions require further development. In this development process inventor cooperation is crucial for commercial success. However, because of a moral-hazard problem with regard to inventor effort, there would be no further development unless the inventor's return and the licensee's output are linked. Jensen and Thursby explicitly propose royalties or equity participation as possible solutions to the moral-hazard problem. Academic spin-offs might be another solution to that kind of moral-hazard problem in technology transfer.

Other studies analyze why transfer channels often suffer from a low speed of technology transfer. Adams (1990) shows that there is an average lag of 20 years from the publication of academic research to its application by industry, whereas Mansfield (1995) finds that for a firm's product or process innovations, which could not have been developed in the absence of recent academic research, 7 years on average elapse between the finding of the relevant academic research results and the commercial introduction of the new product or process.

---

<sup>1</sup>Public research institutions include besides higher education institutes (e.g. universities or technical colleges) also public research organisations (e.g. Fraunhofer Society, Max Planck Society). In the following university, academia and public research institutions are synonyms.

There is a prevalent belief that academic spin-offs are established when the founder is employed at university or directly after he has left the academic institution. In a nutshell, Carayannis et al. (1998, p.3), state the naive view: "Typically, an employee [...] leaves the parent organization, taking along a technology that serves as entry ticket for the new company in a high-tech industry." In fact there is no clear definition of an academic spin-off. Some definitions even explicitly state that academic spin-offs are only those new ventures which have been founded during the time at the research institution or immediately after leaving science (e.g. Pirnay et al., 2003). But substantial technology transfer from academia can take place even years after a founder has left university as Egelin et al. (2003a) show. Early research even included those ventures which were not founded immediately as Pirney cites:

"Roberts considered a venture as a MIT spin-off even if there was a lag of up to nine years between leaving MIT or an affiliate labs and starting the company as long as the technological base of the company was related to research at the lab at the time of employment. (McMullan and Vesper, 1987, p.356)"

Although it is well known that spin-off companies can be started years after having left university, analysis is mostly restricted to those whose founders are still members of the university or have very recently left (e.g. Druilhe and Garnsey, 2004). In a first study for Germany, which tried to reveal both the scope of academic spin-off activities in research and knowledge-intensive industries as well as characteristics of academic spin-off firms, Egelin et al. (2003a) found that one in three spin-offs in research and knowledge-intensive industries that are based on new research results and half of all spin-offs in research and knowledge-intensive industries that are based on academic competencies acquired at universities are established more than five years after the founder has left the academic institution.

This paper aims to analyze the factors that drive this time-lag in the establishment of academic spin-offs. A special focus is put on the existence of complementarities in skills needed to establish spin-off ventures as well as

on the impact of the intensity of technology transfer. In a duration analysis I will show that a longer time-lag is caused by the necessity of assembling complementary skills, either via learning by a single founder or by searching for suitable team members. Furthermore, I find that new ventures are established earlier if the intensity of technology transfer is high, the founders have access to university infrastructure, or informal support by former colleagues.

The paper is organized as follows: This introduction is followed by a short literature review of existing empirical spin-off literature. After that the hypotheses for the empirical analysis are developed, followed by section 4 where the data set is described. Section 5 carries out the empirical analysis and section 6 summarizes the findings and concludes the paper.

## 2 Literature review

The spin-off literature covers a wide field of different topics. Many studies investigate the spin-off phenomenon at the university level. These studies often take a policy view and ask how a region or university can enhance and facilitate spin-off activities (e.g., O'Shea et al., 2005; Powers and McDougall, 2005; Clarysse et al., 2004; Di Gregorio and Shane, 2003; Lockett et al., 2003; Franklin et al., 2001; Steffensen et al., 1999). Often benefits and effects for academia are also investigated. A study of Bray and Lee (2004) found, for example, that holding equity in university spin-offs creates, on average, a ten times higher income for US universities than licensing.

On the micro level, characteristics, development and performance of academic spin-offs (Walter et al., 2006; Müller, 2006) are examined. Besides employment growth, turnover growth, and fund raising (especially venture capital funding), survival is frequently examined. The patent stock at founding as well as the patent scope, for example, significantly increases an academic spin-off's probability of survival (Shane and Stuart, 2002; Nerkar and Shane, 2003).

Rothaermel and Thursby (2005b) found that the number of backward patent citations increases the total amount of funds raised, increases the probability of venture capital financing and lowers the firm's probability of failure. Moreover, strong university linkages of spin-offs located in an incubator to the incubator-sponsoring university reduce the probability of failure but retard timely graduation as well (Rothaermel and Thursby, 2005a).

In some studies characteristics and performance measures of spin-offs are compared to those of non-academic start-ups. Egelin et al. (2003b) for example found that employment in the year of establishment is higher in academic spin-offs than in other ventures of research and knowledge-intensive industries. Furthermore, employment growth of academic spin-offs in the first years after the establishment is considerably higher than the employment growth of other new ventures. Dahlstrand (1997) even found that, after an initial ten-year period, spin-offs grew significantly faster than non-spin-offs. But evidence is mixed: Ensley and Hmieleski (2005) showed that university-based start-ups perform significantly lower than their independent counterparts in terms of revenue growth and cash flow. Similarly Egelin et al. (2007) found that Austrian academic spin-offs have higher probabilities of surviving but do not perform better in terms of employment or turnover growth.

The first typology was provided by Pirnay et al. (2003), summarizing prevalent definitions of spin-off activities.

The location decision of academic spin-offs was investigated in detail by Egelin et al. (2004). Theory suggests that in order to benefit from knowledge-spillover effects spin-offs should locate close to their incubator institution. Egelin et al. (2004) found instead that proximity to incubators is less important for location decisions of German academic spin-offs. Fewer studies examined the spin-off process (Ndonzuau et al., 2002), which help to explain the differences in the time that elapses after the founder has left university.

Time is a rather disregarded factor in the literature of technology transfer, especially in the spin-off literature. Markman et al. (2005) do explicitly

focus on the time factor. They investigate the determinants and effects of innovation speed in university licensing measured as the time elapsed between the disclosure of an invention and the licensing of that invention.

Very few studies give some hints about the impact of being still employed in university after founding a company on firm performance, but they are based on a very small sample size of eight or twelve spin-offs (Olofsson and Wahlbin, 1984; Doutriaux, 1987). To the best of my knowledge there are no studies which have investigated the determinants of the length of the time period that elapses after the founder(s) had left university.

### **3 Hypothesis development**

As technology transfer by means of establishing a company is a complex process with different stages there may be many factors influencing the time that elapses between leaving university and the establishment of a spin-off.

Theoretical explanations on why some founders of academic spin-offs established their firm later than others can be borrowed from the theory developed by Lazear (2004) who explains which people are more likely to establish a business. Lazear's theoretical model states that an entrepreneur has to be jack-of-all-trades. This means that an entrepreneur is less specialized and more a generalist as he must have, at least on a basic level, some knowledge of a wide variety of business areas. Hence, people who tend to become entrepreneurs should have a particular strategy on how to invest in their own human capital. Those whose initial skill endowment is unbalanced should invest in skills in which they are weak. Even those with balanced skills will invest in their skills if the prospective income gain exceeds the marginal costs. Lazear's theory is therefore based on skill complementarities which are especially relevant for entrepreneurs.

If complementarities actually exist, for example, between engineering and management skills, founders have to acquire a whole set of competencies or

search for other specialized team members. A scientist with an unbalanced skill profile has to first acquire complementary skills like management skills before establishing his own venture becomes worthwhile. This is time consuming and affects the length of time between the drop out of academia and the point in time when the venture was established. After leaving university a scientist with a balanced skill profile will therefore venture more quickly than the scientist with an unbalanced skill profile. This allows an adoption of Lazear's theory to explain the founding time-lag of academic spin-offs, because we can examine actual new ventures. Complementarities in skills cause longer time-lags. As acquiring a whole set of knowledge and searching for other specialized team members could be characterized as substitutes, the formation of a team of founders is a useful alternative to acquiring the needed complementary skills. Furthermore, to venture more quickly it is necessary that either a single founder or a team demonstrates a skill profile that is characterized by a combination of skills rather than by specialization in one single subject. Thus the first hypothesis can be expressed as follows:

**Hypothesis 1a:** *Spin-offs established in teams have shorter time-lags between the drop out of academia and the establishment of the spin-off.*

**Hypothesis 1b:** *A combination of different skills leads to shorter time-lags than a homogenous skill profile.*

Concerning the technology or knowledge they transfer, academic spin-offs are quite heterogenous. With regard to the type of knowledge transferred one can distinguish between research results, new developed methods, and skills acquired at university. These types differ primarily in their specificity of knowledge. While the new research results usually have a quite narrow application range for commercial exploitation, the scope is wider for methods and widest for competencies acquired in academia. It is reasonable to assume that the time which elapses after leaving university is highly influenced by the type of knowledge which is transferred. An example will help to illustrate that idea: When the establishment is based on new research findings a spin-off should be founded closer to the time of leaving academia than when

the establishment is based on specific skills acquired at university. The finding of new research results usually opens a *"window of opportunity"* during which the opportunity has to be exploited before the window is "closed" by competitors. This window of opportunity might be rather short depending on the technology developed. The exploitation of skills acquired in academia will in general have a window of opportunity which is much larger than that of successful exploitation of new research results. Hence for securing the competitive advantage the time factor is of more interest when research results are sought to be transferred in marketable products or services than skills.

Because highly specific knowledge requires more effort to transfer, the transfer of research results obviously can be claimed to have a higher intensity of technology transfer which again lessens the "window of opportunity". The second hypothesis can therefore be formulated in terms of intensity of technology transfer.

**Hypothesis 2:** *Spin-offs with a higher intensity of technology transfer have shorter time-lags.*

## 4 Database and Descriptive Statistics

For the following empirical analysis a survey of more than 20,000 German start-ups in research and knowledge-intensive industries founded between 1996 and 2000 is used as data set. In 2001 a computer-assisted telephone survey was conducted in order to estimate both the number of academic spin-offs in Germany and to identify the core characteristics of academic spin-offs. The underlying population from which a stratified random sample was drawn consists of all the new ventures in research and knowledge-intensive industries<sup>2</sup> which had been established between 1996 and 2000. Stratification

---

<sup>2</sup>Research and knowledge-intensive industries include cutting edge technology (e.g. manufacturing of pharmaceutical products), high technology (e.g. manufacturing of chemicals), technological services (e.g. telecommunications) and knowledge-intensive services (e.g. business consulting). A classification based on NACE codes is provided in the appendix.

criteria are the industry, the year of establishment, and the type of region where the start-up was established. Data concerning all start-up companies in Germany could have been retrieved from the Mannheim Foundation Panel which is built upon firm level data made available by CREDITREFORM<sup>3</sup>. One major advantage of that survey is the way academic spin-offs are identified. However, instead of asking technology-transfer offices about spin-off activity at their research institutions, founders themselves were asked about their academic background. Technology-transfer offices and heads of institutions might both have limited information about the amount of spin-off activities at their institutions. In addition they lack information about the characteristics of the founder or the start-ups. Especially for spin-offs that are established years after the founders have left university, the institutions will hardly be informed.

During the interview each start-up was asked about the academic background of the founders and the relevance of academic skills, new scientific methods and results of the founders' own research activities in the establishment process. Academic spin-offs are then those foundations of persons with an academic background (students, graduates and researches) which classified academic skills, new scientific methods or own research results as *indispensable* for the establishment of their firm.

According to these statements three types of spin-offs could be distinguished which differ in their intensity of technology transfer.

**Research-based transfer spin-offs:** New *research results* developed by at least one of the founders must have been indispensable to the creation of the firm (highest intensity of technology transfer).

**Method-based transfer spin-offs:** New *scientific methods*, which at least one of the founders acquired during the time at the public research insti-

---

<sup>3</sup>CREDITREFORM is Germany's major credit rating agency, collecting information about almost all German firms for the purpose of providing information about a firm's financial standing (more detailed information on the Mannheim Foundation Panels is provided by Almus et al. (2000)).

tute, must have been indispensable to the creation of the firm (medium intensity of technology transfer).

**Competence spin-offs:** Merely *specific skills*, which at least one of the founders acquired during the time at the public research institute, must have been indispensable to the creation of the firm (lower intensity of technology transfer).

As this paper aims to investigate the influence of complementarities in skills and the intensity of technology transfer on the length of time which has elapsed between leaving the public research institution and founding the company, the sample is restricted to those firms which could name the institutions they come from and which could provide information on the year when university was left.

Using the above described methodology, out of 20,241 observations of new ventures in research- and knowledge-intensive industries, 1,810 spin-offs can be identified and the time their founders needed to venture can be analyzed. Out of these 1,810 academic spin-offs the sample contains 15% research-based transfer spin-offs, 23% method-based spin-offs and 62% competence spin-offs.

Furthermore, information about the public research institutions, where the founders come from, the subjects studied by the founders, and some general facts about the firm (for example, start-up size, turnover, employment, R&D activities) were retrieved during the interview.

For all spin-offs, whose founders had, up to the time of the survey, already left the public research institute, a kernel density estimation for the time which elapsed between leaving academia and establishment of the spin-off was calculated using the Epanechnikov kernel function. The corresponding graph of the kernel density estimation and the histogram of the time-lag is displayed in Figure 1. The time can even take negative values. This identifies academic spin-offs, in which at least one of the founders was still in academia after the venture was established. The univariate kernel density estimation shows that the distribution of the time to venture is positively skewed. Although the

maximum of the density function is roughly around zero, a high density of time-lags of over 5 years signals that spin-off establishments beyond a time-lag of 5 years are rather probable. One can also see that even time-lags beyond 10 years are relatively probable.

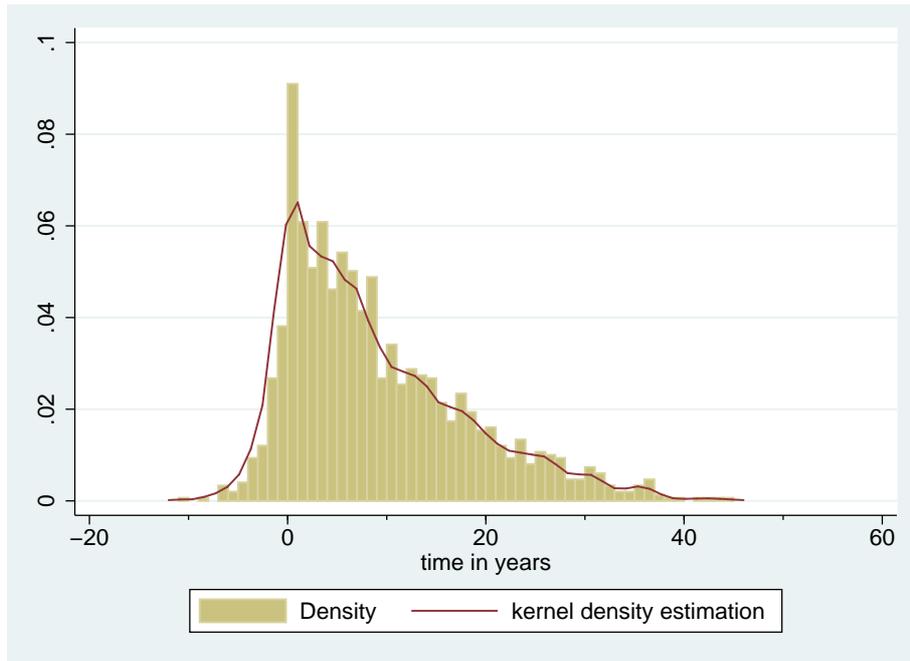

Figure 1: Histogram and kernel density estimation of the time to venture

*Source: ZEW Spin-Off Survey 2001, author's calculations.*

The knowledge and technology transfer via the spin-off establishment is therefore not restricted to those who establish their firm directly after leaving university. Even many years after leaving a public research institute, knowledge and technology transfer may still take place.

Furthermore, descriptive statistics about the time-lag between leaving university and spin-off establishment are given in Table 1. Only about 33% of the spin-offs were established with a time-lag below one year, as one can conclude from the fourth column. For ventures, which were founded a year or more after the founder left university, the period of time which elapsed in between was, on average, around 11 years.

Table 1: Time-lag between leaving university and spin-off establishment

<i>time-lag</i>	<i>Type of spin-off</i>			
	research-transfer spin-off	method-transfer spin-off	competence spin-off	all
founder(s) still in science	41% <sup>A,B</sup>	28% <sup>B,C</sup>	21% <sup>A,C</sup>	25%
established in the year of leaving	10% <sup>A</sup>	10% <sup>C</sup>	6% <sup>A,C</sup>	8%
mean time-lag	10.1 (7)	10.3 (7)	11.2 (9)	10.9 (8)

*Notes:* Median in parentheses; *A:* significant differences between research-transfer spin-offs and competence spin-offs, *B:* significant differences between research-transfer spin-offs and method-transfer spin-offs, *C:* significant differences between method-transfer spin-offs and competence spin-offs.

*Source:* ZEW Spin-Off Survey 2001, author's calculations.

Moreover the descriptive statistics reveal substantial differences in the founding time-lag between the different spin-off types. A spin-off with higher intensity of technology transfer seems to be established closer to the year university was left.

Descriptive statistics on foundation and founder characteristics are presented in Table 2. Around 60 percent of all spin-offs were founded in teams.

Spin-offs can be further distinguished by the founders' positions in the respective research institutes. If none of the founders has been a researcher the spin-off is named student spin-off. While 35 percent of research-based transfer spin-offs were founded by persons who have only been students at the research institute, the fraction for method-based transfer spin-offs and competence spin-offs is much higher (64 percent and 75 percent respectively). Overall 66 percent of the spin-offs had no researchers in the founding team.

In the survey founders were also asked which motivations apply to their decision to start a firm. The overwhelming majority stated that working independently and self-determined was one reason for firm formation (92

percent). Improving one's personal income prospectives was also named by the majority of respondents (64 percent). Another reason to found the firm, which applies to 49 percent of all firms, was a specific corporate demand for products or services. To use the economic potential provided by research results is the case for 17 percent of all competence spin-offs compared to 55 percent of research-based transfer spin-offs. Better career options than in academia is only a minor motivation for competence spin-offs (9 percent) whereas career options seem to be more common for research-based transfer spin-offs (24 percent). That difference, as well as the difference in the exploitation of the economic potential provided by the research results, are statistically significant at the 1 percent level.

Furthermore, it can be seen from Table 2 what share of spin-offs received different kinds of support from their academic institutions prior to firm formation. The different kinds of assistance vary from courses, infrastructure and individual legal and business advice, to the establishment of contacts and encouragement and support from colleagues. Around 6 percent made use of courses and teaching events relevant for the founding process while 4 percent received individual legal or business advice. For these types of support from academic institutions before founding no significant differences between the spin-off types can be found. Provision of infrastructure (offices, secretarial service, access to laboratories etc.), establishment of contacts and encouragement and support from colleagues was the more frequently used the higher the intensity of technology transfer. 26 percent of research-based transfer spin-offs got support from colleagues while only 16 percent of method-based transfer spin-offs and 10 percent of competence spin-offs received that kind of support. This applies for provision of infrastructure and establishment of contacts, too. 12 percent of research-based transfer spin-offs, but only 5 percent and 3 percent of method-based transfer spin-offs and competence spin-offs respectively, were supported with infrastructure. Contacts were established for 10 percent of all research-based transfer spin-offs, but just for 7 percent (5 percent) of all method-based transfer spin-offs (competence spin-

offs). The highlighted differences can be explained by a selection process of the supporting university because high-potential start-up ideas are supported preferentially. Furthermore, the differences are significant at least against the one-sided alternative.

The founder(s) studied mostly one single subject (76 percent). Subject combinations are divided into four categories: a combination of natural science and engineering, a combination of natural science and business, a combination of engineering and business, and other combinations. With a fraction of about 13 percent other combinations are the most frequent category. The corresponding fractions of the other categories classified by the spin-off type can be inferred from Table 2 as well. Even if an spinoff was not established by a team of founders, the founder could have studied various subjects. In fact, 4% of all single founders show a combination of subjects. The other way around, team foundations do not necessarily show a combination of different subjects.

Research and knowledge intensive industries can be further subclassified into six industries: the cutting edge technology industry, the high technology industry, the software industry, technological services, knowledge intensive services and other manufacturing industries. The majority of the firms operate in technological services (38 percent), closely followed by knowledge intensive services (37 percent). Altogether 7 percent operate in cutting edge technologies, while the fraction of research-based transfer spin-offs operating in cutting edge technology is almost twice as high (13 percent).

Table 2: Descriptive statistics

<i>variable</i>	<i>Type of spin-off</i>			all
	research-based transfer spin-off	method-based transfer spin-off	competence spin-off	
team	57%	58%	61%	60%
student	35%	64%	75%	66%

## 5 Empirical Analysis

### 5.1 Estimation Method

In order to analyze the time to the occurrence of an event it is appropriate to deviate from the normality assumption and use techniques of survival analysis. To estimate the effect of certain covariates  $\mathbf{x}_j$  on the hazard rate  $h(t|\mathbf{x}_j)$ , which is the instantaneous rate of failure<sup>4</sup> at a given time  $t$  or the age specific failure-rate, most commonly proportional hazard models, expressed by

$$h(t|\mathbf{x}_j) = h_0(t) \exp(\mathbf{x}_j \boldsymbol{\beta}_x),$$

are used.

As the baseline hazard  $h_0(t)$ <sup>5</sup> is time-dependent, but not influenced by the covariates, each individual (firm) faces the same baseline hazard. Because of that, comparing subject  $j$  to subject  $m$ , one obtains from the model

$$\frac{h(t|\mathbf{x}_j)}{h(t|\mathbf{x}_m)} = \frac{\exp(\mathbf{x}_j \boldsymbol{\beta}_x)}{\exp(\mathbf{x}_m \boldsymbol{\beta}_x)},$$

which is called hazard ratio. The hazard ratio is constant, assuming that the covariates  $x_j$  and  $x_m$  do not change over time.

From the formulation of the hazard rate it is easy to see that for a binary covariate  $x_k$  shifting from zero to one the hazard ratio is

$$\frac{h(t|\mathbf{x}_j, x_k = 1)}{h(t|\mathbf{x}_j, x_k = 0)} = \frac{\exp(\mathbf{x}_j \boldsymbol{\beta}_x + 1 \cdot \beta_k)}{\exp(\mathbf{x}_j \boldsymbol{\beta}_x)} = \exp(\beta_k),$$

which gives the coefficients an easy interpretation. As a semi-parametric estimation method proposed by Cox (1972) imposes no restrictions on the

---

<sup>4</sup>The risk of failure is the risk of the occurrence of the event under investigation, i.e. here the "risk" of establishing the spin-off.

<sup>5</sup>The baseline hazard is the hazard rate of observations with zero covariates. The covariates shift the baseline hazard multiplicatively.

shape of the baseline hazard and therefore allows the baseline hazard to be as flexible as possible, Cox regression is used for this analysis.

Using survival analysis the time under investigation is not allowed to take negative or zero values. Therefore, concerning the dependent variable no difference is made between all spin-off establishments which are founded in the time when the founder was still in academia. These observations are assumed to enter and "fail" immediately and a time value of 0.1 was assigned to them. Similarly all firms whose founders left academia in the year of establishment (original time value of zero) got a new time-value of 0.2. For all other observations (these with a time-lag) the time-lag was measured in years. This procedure is possible because the Cox proportional hazards model is sensitive only to the order of the failure events. Thus as long as one keeps the earliest failure events as occurring first, the results will remain unchanged.

In order to test Hypothesis 2 the intensity of technology transfer is measured by the different spin-off types. The effect of complementarities in skills (Hypotheses 1a and 1b) is captured by a dummy variable which indicates if the spin-off was established by a team and a set of dummy variables which display the combination of subjects the founder(s) studied, provided the founder(s) did not study a single subject<sup>6</sup>.

But the time lag between leaving university and establishing the firm can be influenced by several other factors. To capture these effects a wide set of further dummy variables is included in the analysis. These dummies portray if the founders were students or researchers during their time in academia, which motivations had driven the establishment, what kind of support the founders received from their academic institution, and to which economic sector the spin-off belongs.

Tests based on Schoenfeld residuals (Schoenfeld, 1982; Grambsch and Therneau, 1994) reveal some violations of the proportional hazard assumption

---

<sup>6</sup>These are different aspects as one founder could have studied several subjects of a team of founders could have studied the same subjects.

concerning the covariates *method-based spin-off* and *student*. Therefore another model (model B) is estimated with the same specification as in the original model (model A) but stratified by the variables *method-based spin-off* and *student*. In contrast to the standard Cox model, which assumes proportional hazards for each explanatory variable, a stratified model makes it possible to control for the effect of a certain variable without making a proportional hazard assumption for that variable (Parmar and Machin, 2006). Stratification allows for different baseline hazards for each of the possible categories<sup>7</sup> but constrains the coefficients to be the same. The model is now relaxed in favour of

$$h(t|\mathbf{x}_j) = h_{0i}(t)\exp(\mathbf{x}_j\boldsymbol{\beta}_x), \quad \text{if } j \text{ is in group } i, \quad i = 1, 2, 3, 4.$$

Tests on the proportional hazard assumption do not reveal further violations. Because analysis in model B is stratified by the variables *method-based spin-off* and *student* the effect of these variables is now absorbed by different shapes of the baseline hazard and no coefficients are estimated.

## 5.2 Estimation Results and Discussion

Estimation results of the Cox regressions for both models are summarized in Table 3. Both coefficients and standard errors are presented. As reference categories the categories with the highest fraction are used (competence spin-off, single academic subject profile, technological services). Between the two models the coefficients considerably change neither in magnitude nor in significance which indicates that the violation of the proportional hazard assumption in model A was not severe.

Both hypotheses stated in section 3 can be supported by the data. The hazard ratio for the team dummy is  $\exp(0.205) = 1.23$ . This means that

---

<sup>7</sup>Because *student* and *method-based spin-off* are binary, four combinations appear and the model allows four different baseline hazards.

the hazard increases by 23% if the spin-off is founded by a team instead of a single founder. Hence the time lag is considerably shorter for spin-offs established by a team of founders. Significant positive effects of two of the subject combination dummies show that the time-lag is highest for those who studied one single subject, which is the reference category. Combinations like natural science with engineering or business have considerably higher hazards, i.e. the probability that the spin-off establishment takes place is higher for those combinations than for a single founder at any point in time. The hazard increases by 24 percent or 23 percent, respectively, compared to those spinoffs which were founded without subject combinations. These effects support the assumption that complementarities in skills are present and notably relevant in the establishment process of academic spin-offs.

In addition to acquiring complementary skills by team formation the positive effect of teams on transfer speed can also be explained by the pooling of financial resources and risk-sharing among the team members both of which reduce the risk faced by the individual founder.

Furthermore a research-based transfer spin-off has a hazard which is  $\exp(0.140) - 1 = 15\%$  higher than the hazard of a competence spin-off. A spin-off with a higher intensity of technology transfer is therefore established more "quickly". This supports Hypothesis 2.

Further, the coefficients of the control variables reveal some interesting insights. Among potential motivations for the spin-off establishments, the motive to work independently and making one's own decisions speeds up establishment, which is quite intuitive. The hazard for founders driven by this motivation was about 25% higher. Likewise the motivation to take promising economic opportunities provided by research results has a positive influence on the technology transfer speed. Those who were motivated by the economic potential provided by research results have a hazard which is 12% higher. This motivation might accompany the findings about the effects of transfer intensity.

Concerning the support received from academic institutions, significant influence can be found for infrastructure support and encouragement by colleagues and professors. While the provision of infrastructure influences the time-lag substantially, the encouragement of colleagues, which is more a soft-kind support, is even more important for the acceleration of technology transfer through academic spin-offs. The provision of infrastructure increases the hazard by 38% while encouragement of colleagues increases the hazard by 54%.

These two kinds of university support differ materially. Support of infrastructure is an institutionalized assistance and positive effects on transfer speed are quite obvious as start-up costs are reduced substantially when existing infrastructure can be utilized. The explanation for the rather large effect of encouragement of colleagues and professors is not that obvious. The results of the empirical analysis suggests that psychologic factors such as peer support and climate effects are rather important in the start-up decision process. First, encouragement of colleagues helps opportunity identification. Somebody who has never thought about being self-employed will need much more time to recognize his research results or skills as having the potential to be commercialized by the establishment of a new firm. The idea that his former scientific work provides the basis for a business idea might not show itself until the researcher has gained some market experience. If the scientist got in contact with some "spirit of entrepreneurship" during his time at academia this recognition process will be substantially accelerated. In this context colleagues act as guides.

Second, support from colleagues means professional assistance, too. Besides the possible acceleration of the opportunity identification process by support from colleagues, the founder knows that she can fall back on the knowledge of former colleagues on an informal basis.

The sector dummies show that there are also substantial technology transfer speed differences between the sectors. Academic spin-offs operating in the software industry are established closest to the time being in academia. To

explain that result one has to remember that all spin-offs in the sample had been established between 1996 and 2000, the time of the "New Economy boom". During that time it was rather easy for firms in information technologies, especially for software-firms, to find an investor and receive funding. A fact which accelerates foundation substantially.

As the variable method-based transfer spin-off is insignificant in model A, no valuable information is lost by using this covariate as stratification criteria in model B. But model A indicates that the academic status of the founder when he obtained the results or skills, which have been essential for the business idea, has a significant impact on transfer speed. If the founder was not a researcher but a student, the hazard is about 36% lower in model A. The time-lag is thus longer for "students only" founders.<sup>8</sup> This result is quite intuitive as students and graduates, which have never worked in a research institution, have not spent as much time in science as researchers. Hence "students only" founders must use market experience as a substitute for the experiences a researcher could gain in academia. Although the stratified Cox regression cannot give a precise estimate about the magnitude of the effect of the academic status, a comparison of the estimated cumulative baseline hazards supports the findings of model A. The cumulative baseline hazard of researchers lies above the cumulative baseline hazard of establishments which are made only by students and graduates (see appendix A).

As a goodness of fit measure an evaluation based on Cox-Snell residuals (Cox and Snell, 1968) was used.<sup>9</sup> For both models a good fit could be observed (see appendix B), but the unstratified model (model A) has a slightly better fit than the stratified model (model B).

---

<sup>8</sup>The lower the risk of "failure" the longer the time between leaving academia and establishment.

<sup>9</sup>For models which fit the data well the Cox-Snell residuals ought to have a standard exponential distribution with a hazard function of one for all  $t$ . Accordingly the cumulative hazard of the Cox-Snell residuals should form a straight 45 degree line. The cumulative hazard function of the Cox-Snell residuals is usually estimated using the Nelson-Aalen estimator.

## 6 Conclusions

This paper focuses on the phenomenon that a large amount of technology transfer by means of academic spin-off creation is done years after the respective founders had left the academic institution. A fact which was in general known but ignored in the existing spin-off literature. This "late" technology and knowledge transfer is not unimportant. New academic research results, methods or skills obtained by founders in research and knowledge intensive industries had been indispensable for the creation of the spin-off even more than ten years after the institution was left. Policy makers should therefore not only concentrate on direct spin-off activity but also develop appropriate programmes for academic persons who first acquired complementary competencies such as market experience.

The empirical analysis shows that skill complementarities are likely to be present in the spin-off establishment process. This conclusion is drawn from both the fact that the time-lag of spin-off establishments in teams is shorter than the time-lag of single founders and from the positive effect that certain combinations of academic subjects have on transfer speed. As team foundations have significantly shorter time-lags, a good matching of potential founders with persons with a complementary skill profile can foster spin-off creation. Policy makers as well as technology transfer offices should take that into account and offer assistance in the matching process.

Additionally, the intensity of technology transfer appears to speed up the transfer process due to a smaller "window of opportunity". For example, because of potential imitation, spin-offs with a high intensity of technology transfer were established earlier than those with a low intensity of knowledge transfer.

The positive influence of university infrastructure support and support from colleagues and professors on transfer speed give further suggestions to policy makers on how to encourage direct spin-off establishment. While more formal support by means of providing infrastructure helps to speed up spin-

off formation, "peer support" by means of encouragement of colleagues and professors is also crucial factor for the time-dimension in the spin-off process.

As this paper assumes that the founders acquire complementary skills in the time between academia and spin-off formation it would be interesting for further research to know which competencies exactly can be termed complements. Is market experience, management experience or professional research experience in commerce of higher relevance? What are the influences of general life experience and periods of unemployment? Furthermore, the reasons for very long time-lags, such as time-lags of more than ten years, and the consequences of such long time-lags on firm-performance can be investigated. Thus, a lot of open questions concerning the time-lag remain which should be addressed in the future.
