## October 2006

## MOTIVATION

There is a large and positive correlation between education and health.

This result is extremely robust
It remains unclear whether better health actually causes higher education levels, or whether it is a spurious correlation

Two Major Challenges in Identifying the Role/Impact of Health on Academic Outcomes:

Endogeneity and Measurement Error.
Substantial Public Policy Implications
-Rationale for Medicaid in the US and Introduction of Medicare in Canada

## KEY POINTS

We will discuss how we can use a set of genetic markers to identify the impact of adverse health on education.

We will have some clear answers but propose more questions:
-Large impact of poor health on academic performance. -Substantial heterogeneity exists across gender; Girls really suffer from poor health.
-Comorbidity of health disorders and health behavior must be accounted for.
-Genes show great promise as good instruments.

## SCIENCE

Lots of evidence suggest that the role of genetic factors leading to poor health outcomes is substantial.

As a result, pharmaceutical companies regularly develop drugs that target specific genetic markers.

Bupropion (a.k.a. zyban) affects dopamine production. Ritalin blocks the reuptake of dopamine.

Different regions of the brain engage in different processes.
Many correlates of risky behaviors as well as mental and physical disorders are found in the brain's reward system.
This system regularly operates by sending messages via neurotransmitters from the VTA to the prefrontal cortex.

Some food and drugs have properties that hijack this system and give individuals a feeling of pleasure.

## NEUROANATOMY

## GENETIC MARKERS

Each person inherits an allele of a gene from each parent at conception. The two alleles combine to form a marker.

Terminology
Polygenic
Homozygous vs. Heterozygous
Polymorphism
Example: the Dopamine Receptor D2 locus. People in general either have A1/A1 or A1/A2 or A2/A2.
A1 alleles code for reduced density of dopamine receptors.

## Control subjects

These composime brdin scan mages show that obese notwiduals have significamy kever chopamme receptors in the outhocd ared than conool subyects. These receptors trament pieas-
 hive bexen found in people wheleted to drege of abuse. The revterced rewod experienced by people whe this devichocy nay make then more bety to engnge in mblucthe bebaviors.
http://www.drugabuse.gov/NIDA_Notes/NNVol16N4/pathological.html

Our data contains information on three other genes

- SLC6A3 codes for the dopamine transporter protein involved with reuptake. (DAT 0, 1, 2)
- Trypthohan Hydroxylase Gene is involved with mood and impulse as it synthesizes serotonin. (TPH AA, AC, CC)
- CYP2B6 gene metabolises drugs and toxins in the liver. (CYP TT, CT, CC)

Interactions of these markers could have powerful effects.

## DATA

Our primary data source is the Georgetown Adolescent TObacco Research Study

## GATOR Study

Information on Genetic Markers:
-Buccal swabs with standard techniques. Four markers were collected and double-checked at 20\%.

Four follow-up surveys with the students were conducted.
Each survey conducted at school contains standard demographic information and detailed smoking information.
Academic performance collected in the last three surveys. Very little attrition -- Follow up is 95\%, 96\%, 93\% and 89\%.

## HEALTH MEASURES

## (Table 1)

Depression assessed by the CES-D scale. Well-established 20 item questionnaire. Use adolescent cutoffs that vary by age and gender.
To assess ADHD as well as AD and HD separately, the Current Symptoms Scale Self-Report Form was used. Only known to the researchers; AD/HD; reduce measurement error.
Obesity is constructed from self-reported height and weight collected in the fifth survey. Not ideal.
All means fall within normal ranges for adolescent samples.
We matched by school identifiers to CCD and census records by zip codes for additional controls.

## EMPIRICAL FRAMEWORK

Focus is to construct a model from health to education that allows for adolescent making some decisions.
Step 1. Adolescent chooses whether or not to engage in a health behavior to maximize her utility:

$$
k_{i T}=k\left(X_{1 i T}, p_{k,} G_{i,}^{k} H_{i T-1,} \varepsilon_{i T}^{k}\right)
$$

Step 2. Altruistic parents observe a signal of their child's health behavior ( $\dot{\kappa}$ ) and make health input decisions ( $I_{i T}$ ) that enter into a health production function for the adolescent:

$$
H_{i j T}=g\left(X_{2 i T} \ldots X_{2 i 0}, K_{i T} \ldots K_{i 0}, I_{i T} \ldots I_{i 0}, H_{i 0}, G^{H}{ }_{i,}, \varepsilon_{i T}^{H} \ldots \varepsilon_{i 0}^{H}\right)
$$

For simplicity, assume parents have a single mindedness in preference towards their child's health:

$$
\mathbf{U}\left(\mathrm{H}_{\mathrm{iT1},} 1^{\cdot}\right) \geq \mathbf{U}\left(\mathrm{H}_{\mathrm{iT} 2},^{\cdot}\right) \quad \text { if } H_{i T 1}>H_{i T 2}
$$

Step 3. Altruistic parents choose education inputs such as the optimal school for the child, whether or not to hire tutor etc. that will maximize household utility.

Conditional on the selection of inputs in step 3, adolescent achievement is obtained through an education production function:

$$
A_{i j T}=f\left(X_{i T}^{e} \ldots X_{i 0,}^{e}, Q_{j T} \ldots Q_{j o r}, H_{i T}, U_{i r} \varepsilon_{i T}^{e} \ldots \varepsilon_{i 0}^{e}\right)
$$

## HEALTH AS AN EDUCATION INPUT

Directly

- Physical energy a child has for learning.
- Affects child's mental status: ability to concentrate.

Indirectly

- Child's health status may affect the response of peer, parents and teachers; thus influence the inputs in education.

Possible Dynastic Effects

- Potential proxy for the part of family inputs caused by the same symptoms in parent(s) and sibling(s).

## ESTIMATION

Linearize the education production function:

$$
A_{i j T}=\beta_{0}+\beta_{1} X_{i T}^{e_{i T}}+\beta_{2} H_{i T}+\beta_{3} \mathbf{Q}_{j T}+\varepsilon_{i j T}
$$

Similarly health production and decision to engage in risky behavior

$$
\begin{aligned}
& H_{i T}=Y_{0}+Y_{1} X^{H}{ }_{i T}+Y_{2} k_{i T}+Y_{3} G_{i}^{H}+\varepsilon^{H}{ }_{i T} \\
& k_{i T}=\delta_{0}+\delta_{1} X_{i T}^{k}+\delta_{2} H_{i T-1}+\delta_{3} G_{i}^{k}+\varepsilon_{i T}^{k}
\end{aligned}
$$

This creates a system of equations.

## IDENTIFICATION

Use genetic markers as instruments.

## IDENTIFICATION DETAILS

Which genes to pick?
There does not appear to be a systematic relationship between the genes. (Table 2)

The raw data shows that unhealthy kids have significantly lower GPAs. (Table 5)

Genes are strongly related to health outcomes and behaviours. (Table 3)

Additional challenge is presented by comorbid conditions. (Table 4)

We consider two health vectors in our analysis.

Table 2: Number of Individuals with Each Genetic Marker

| Genetic Markers | Genetic Marker Alleles | Number Of People with each allele | Interaction with the rare alleles |  |  |  |

Note: Each cell contains the number of individuals diagnosed with the respective row and column combination.

[^0]
## RESULTS I

(Table 5) OLS estimates suggest

- Each health disorder is negatively and significantly associated with academic performance for the full sample.
- Large Negative impact of obesity on GPA for females.
- Boys' GPAs have a strong negative association with AD.
(Table 7) 2SLS estimates suggest
- Depression and obesity is significant for the full sample.
- Large offsetting impacts of AD and HD
- Substantial heterogeneity across genders:

The negative impact of poor health is substantial for girls.
Nothing is significant for boys.
(Appendix Table 7) 3SLS estimates results not different from 2SLS; little efficiency gains.

Hausman tests reject the exogeneity of the health vectors.

Note: Corrected standard errors in parentheses. Regressions include parental age, parental age squared, parental gender, indicator for whether the responding parent is a biological parent, school and time period indicators. ${ }^{* * *},{ }^{* *}$, * denote statistical significance at $1 \%$, $5 \%, 10 \%$ level respectively.

## DISCUSSION OF 2SLS RESULTS

These are reduced form coefficients
The coefficient estimates may capture a dynastic and cumulative effect of the impact of health disorders

The dynastic effect may be desirable

- Assortative mating critique

The availability of genes as instruments makes it crystal clear the level of difficulty in obtaining structural parameters

Yet even if possible - may be uninteresting
Compare to within twins strategies (epigenic modication)
Robustness to parental smoking and inclusion of parental characteristics.

## RESULTS II

First stage regressions
For each subsample the $F$ statistic is above current cutoffs for weak instruments for each health outcome and health behaviour.

Overidentification tests
J tests provide little evidence against the overidentifying restrictions.

The results suggest that statistically genes are promising instruments.

## ROBUSTNESS

Results are robust to alternative genetic instrument sets.
Some have better first stage properties for the two subsamples than others.

Appendix Table 2.

Table 6: Summary Information on the Performance of the Instruments

|  | Full Sample | Females Only | Males Only | Full Sample | Females Only | Males Only |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| First Stage F statistics |  |  |  |  |  |  |
| Full System | 19.01 | 12.03 | 9.25 | 19.14 | 12.84 | 9.33 |
| ADHD | 10.61 | 8.13 | 5.37 | N/A | N/A | N/A |
| AD | N/A | N/A | N/A | 14.37 | 8.19 | 10.20 |
| HD | N/A | N/A | N/A | 8.66 | 11.83 | 6.70 |
| Depression | 12.20 | 5.18 | 10.41 | 12.20 | 5.18 | 10.41 |
| Obesity | 10.16 | 11.32 | 11.39 | 10.16 | 11.32 | 11.39 |
| Smoking | 7.33 | 7.27 | 6.30 | 7.33 | 7.27 | 6.30 |
| P -values from Overidentification Tests |  |  |  |  |  |  |
| Full System | 0.611 | 0.278 | 0.386 | 0.217 | 0.236 | 0.486 |
| ADHD | 0.553 | 0.420 | 0.236 | N/A | N/A | N/A |

| HD | N/A | N/A | N/A | 0.845 | 0.812 | 0.266 |
| Depression | 0.773 | 0.822 | 0.465 | 0.773 | 0.822 | 0.465 |
| Obesity | 0.216 | 0.232 | 0.817 | 0.216 | 0.232 | 0.817 |
| Smoking | 0.2 | 0.874 | 0.421 | 0.52 | 0.61 | 0.29 |

## RESULTS III

What if we do not account for endogenous health behaviour?

- The impacts of all health outcomes on GPAs increase markedly. (Table 8)
- In addition, depression now comes in significantly for boys.
- Hausman tests reject the exogeneity of smoking decisions.
- The different outcomes may be a result of different smoking patterns. In particular, boys with AD, HD and Depression smoke more frequently than girls with same disorders, and with more tar and nicotine content.
- Compensating benefits from smoking?

Table 8: Two Stage Least Squares Estimates of the Achievement Equation where Years of Smoking is Treated as Exogenous

|  | Full <br> Sample | Females <br> Only | Males <br> Only | Full <br> Sample | Females <br> Only | Males <br> Only |
| :--- | :---: | :---: | :---: | :---: | :---: | :--- |
| ADHD | $-0.646^{*}$ | $-0.672^{* *}$ | 0.010 | N/A | N/A | N/A |
| $(0.343)$ | $(0.287)$ | $(0.345)$ |  |  |  |  |
| AD | N/A | N/A | N/A | $-1.18^{* * *}$ | $-1.46^{* * *}$ | -0.414 |
|  |  |  |  | $(0.408)$ |  |  |
| $(0.393)$ | $(0.428)$ |  |  |  |  |  |
| HD | N/A | N/A | N/A | 0.611 | 0.220 | 0.108 |
|  |  |  |  | $(0.588)$ | $(0.420)$ | $(0.613)$ |

## RESULTS IV

What if We Ignore Comorbid Conditions?
We consider 2SLS estimates that include one health variable at a time. (Table 9)

- The impact of ADHD becomes larger and significant. Approximately equal to size of depression and obesity impacts.
- The impact of depression is approximately 40\% larger.

Results suggest that even with valid instruments such as genetic markers biases regarding measurement error is still a concern.

Proper measures of health require a rich vector.

Table 9: Two Stage Least Squares Estimates of the Achievement Equation Including A Subset of Health Outcomes

| Include <br> health <br> behaviors | Full <br> Sample | Girls | Boys |
| :--- | :---: | :---: | :---: |
| ADHD | -0.351 | -0.319 | 0.284 |
|  | $(0.319)$ | $(0.359)$ | $(0.452)$ |
| AD | 1.392 | 0.648 | 0.615 |
|  | $(0.669)^{* * *}$ | $(0.633)$ | $(0.546)$ |
| HD | -1.966 | -1.040 | 0.237 |
|  | $(1.183)^{* * *}$ | $(0.609)$ | $(0.911)$ |
| AD | 0.529 | -0.124 | 0.766 |
|  | $(0.304)$ | $(0.400)$ | $(0.383)$ |
| HD | -0.144 | -0.330 | 0.972 |
|  | $(0.517)$ | $(0.445)$ | $(0.766)$ |
| Depression | -0.713 | -1.250 | -0.032 |
|  | $(0.302)^{* *}$ | $(0.455)^{*}$ | $(0.391)$ |
| Obesity | -0.331 | -0.352 | 1.067 |
|  | $(0.329)$ | $(0.235)$ | $(0.738)$ |
| Observations | 2576 | 1366 | 1210 |

Note: Corrected standard errors in parentheses. Each cell of the table corresponds to a separate regression. The dependent variable of the regression differs by row. Columns reflect different samples.
Regressions include the non-health inputs in Table 7, school and time period indicators.
*, **, *** denote statistical significance at $1 \%, 5 \%, 10 \%$ level respectively.

## CONCLUSIONS

1. Genetic markers are promising as instruments.
2. The impact of poor health outcomes on academic achievement is large (one s.d.) with substantial heterogeneity across genders. Why?
3. When investigating the impact of health status on education, it is important to account for endogenous health enhancing or health deteriorating behaviors.
4. The presence of high comorbidity of adverse health outcomes is striking which presents a challenge to properly control them all.

## DIRECTIONS FOR FUTURE RESEARCH

Understanding the heterogeneity across genders
Differences in self-perception (?), discriminating inputs
(?), impact of physical disorders on energy levels (?)

[^0]:    ${ }^{1}$ For ADHD nothing else excludes AD and HD.
