Abstract:

This paper confirms the existence of peer effects in a learning process with data from an experiment. The experimental setting offers an insight into the mechanisms of peer interaction and provides complementary information to empirical studies using survey or administrative data. The results show that a partner has a motivational effect even before the actual cooperation takes place. The evidence for optimal group composition is not robust. Some of the "better" students improve the performance of their partner but they induce lower motivation.

1 Introduction

It is a long-standing hypothesis that the performance of a student depends on the behaviour and characteristics of his fellow students. The existence and properties of these peer effects affects the welfare implications of educational policies which influence the (self-)selection of students into different learning groups (Arnott and Rowse (1987)). Therefore, Rothschild and White (1995) describe education as a customer-input-technology. However, the identification of peer effects in field data is very difficult. Econometricians invest great effort to identify quasi-experimental evidence on peer effects from administrative or survey data. The ideal data set would observe the same individual at the same time in the same environment but with a different peer. Such a data set is not available. Hence, researchers actually face a trade-off between internal and external validity. Either they take non-experimental data from surveys or administrations and turn them into quasi-experimental evidence as far as possible. Almost all contributions in the literature have followed this part. As an alternative, they generate data in an experiment with key characteristics of a real world learning process.

In this paper I take this second path which is complementary to the econometric approach. The experiment circumvents four problems which typically restrict the analysis of peer effects with field data:

(i)   Students are not randomly assigned to their peer groups. Parents, schools or administrations decide where students enrol. Such a selection process often precludes the identification of a plausible counter-factual result. The econometric literature provides various approaches to this problem. Gould et al. (2005), Hoxby (2000), and Ammermüller and Pischke (2006) for example rely on differences in the compositions of individual classes. Hanushek et al. (2003) and McEwan (2003) use variation within peer groups over time to identify peer effects. Stinebrickner and Stinebrickner (2006), Foster (2006), Zimmerman (2003) and Sacerdote (2001) investigate peer effects in universities in a different way. They use the random assignment of students into university dormitories as indicators for social tie formation and its subsequent impact on educational performance..

(ii)   Teacher behaviour and other environmental characteristics can change with the peer group composition. The same teacher may teach the same topic in a

different way, if the average ability or the ability distribution changes in a class[1].

(iii) Measures for peer effects have to be exogenous. The reflection problem (Manski (1993)) could be ignored if an independent, and relevant, measure for each student was available. Yet most datasets do not have such a variable.

(iv) Even with a satisfactory dataset the mechanisms of peer effects are difficult to identify. Survey or administrative data largely provide a 'peer group composition effect'. This effect does not explain *how* students influence each other and what happens if students do not cooperate at all.

The experiment in this paper covers a learning process. The subjects face a task on which they can improve over time. I used a logical puzzle game called Kakurasu (description see below). Some subjects can improve with a randomly assigned partner (pair treatment), others have to do it alone (single treatment). The assignment to the treatments is random as well. Environmental conditions do not change over time and there is no teacher. Hence, any difference in performance between both treatment groups at the end of the experiment derives from the differences in the treatment.

Beside this identification of a peer effect, the experiment allows an insight into the mechanisms of peer interaction. It is obvious that a single experimental design cannot capture all characteristics of peer effects as they are discussed in the literature (peers as tutors, motivators, benchmark etc.). Experiments help to disentangle the complex interaction mechanisms which are summarized in the catch-all term 'peer effects'. The focus in this paper is on the motivational aspects of cooperation during a learning process.

Cooperation can influence learning processes in several ways. Students help or distract each other, for example. This means in the context of this experiment that the subjects may explain the task to each other. Such an instructional argument is a standard assumption for peer effects in models of educational production. The resulting benefit typically differs with the composition of the peer group. High ability students are assumed to provide a greater advantage, for example. The anticipation of this advantage can provide motivation. If the abilities of the partners are complementary inputs (like in De Fraja and Landeras (2006)) the marginal gain from investing effort is obviously lower in the single treatment groups, Of course the subjects may also distract each other. Lazear (2001) focuses on disadvantage from

---

[1] Arguably, such an effect is part of a peer effect. One could distinguish between a direct peer effect, where students directly influence each other, and an indirect one, where students influence each other via the teacher.

fellow students via the interruption of instruction, but this does not change the logic of the argument.

However, a partner can motivate even if the basic learning technology of single learner and pairs do not differ significantly. People do not want to appear as being a lazy, for example. This aspect has largely been ignored in the literature on the economics of education. Falk and Ichino (2006) find experimental evidence for positive peer effects in a "real task", non-cooperative production environment. In their case the peer effect stems from the mere presence of another person in the same room doing the same job. They relate their approach to the "social facilitation paradigm", a research topic in the psychological literature (e.g., Zajonc, 1965, Cottrell et al., 1968, or more recently Feinberg and Aiello, 2006). Mas and Moretti (2006) find similar results with personnel data from a grocery chain. Social pressure apparently causes the motivation.

Evidence for the motivational aspects of peer interaction in this experiment is provided by a pre-treatment performance test. The subjects know if they will cooperate or not but cooperation has not yet taken place. A second performance test after the treatment provides information about the overall peer effect. The key difference to Falk and Ichino (2006) is the timing of measurement. In their experiment, the subjects face different contexts during the measurement period. In contrast, the participants in this experiment face the same context in the measurement period but differences in the preparation period. To use the educational terminology, the tests are standardized but the learning environment differs. In this context the experiment is without precedent in the economic literature. I did not find anything similar in other disciplines like sociology, psychology or education.

The results show a significant peer effect. Subjects with a partner performed better in both tests. The results provide evidence for the motivational impact of peers since the subjects with a prospective partner are already better in the first test than those subjects in the single treatment group. The results provide only little evidence with respect to an optimal group composition but motivation increases with the ability of the partner. Students with an interest in logical puzzles and good performance in math improve the final test score of their partners but they induce lower motivation. This result is a possible explanation why different econometric studies come to contradicting solutions about the properties of peer effects.

The paper is organized as follows. The next section describes the experimental design. Section 3 presents the results and section 4 concludes.

2 The Experiment

2.1 Design of the experiment

The implementation of the peer effect design is rather straightforward (see figure 1). The subjects faced a learning process for a specific task. The task was a largely unknown logical puzzle called Kakurasu which will be described in greater detail below. The participants were assigned to their treatment groups and, in case of the pair treatment, their prospective partner. They then received some general rules (see appendix) and faced a first test about the task. The test measured how many puzzles the subjects solved in 15 minutes. The assignment to the treatment groups before the first test allows the identification of motivational differences between the treatment groups.

After the first test, subjects could prepare for 20 minutes for a second test. In this preparation period the treatment took place. Some subjects had to prepare alone (single treatment), others with a partner (pair treatment). All subjects got further puzzles, pens and writing paper. The subjects in the pair treatment were allowed to talk to their assigned partner during this preparation period. The subjects learned at the beginning of the experiment about their treatment and the prospective partner.

After the preparation period the second test started. Again, the test measured how many puzzles the subjects solved in 15 minutes. However, the puzzles were more difficult in this test. Questionnaires were handed out before and after the experiment.

Figure 1: The design of the experiment
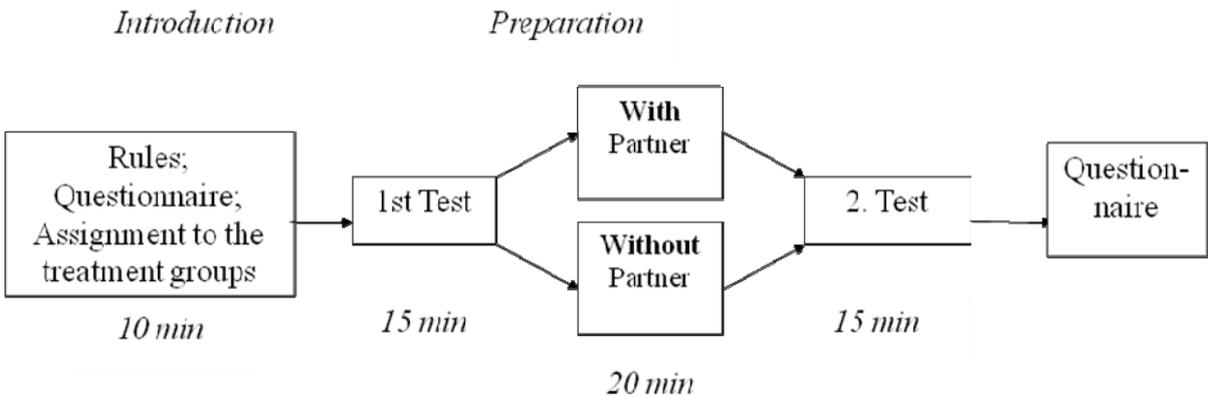

The existence of peer effects is confirmed if the treatment groups differ significantly in the performance in the second test. If the treatment groups differ in the first test, a prospective

partner induces higher effort, even if he does not provide support. In this case the motivational mechanism works. The composition of a learning group matters if the performance of a subject in the pair treatment group increases or decreases with some exogenous characteristics of the partner.

2.2 The Task

In the experiment the participants can learn a solution strategy for a logical puzzle called Kakurasu (see appendix[2]). This type of puzzle consists of a matrix in which the correct fields have to be marked. Numbers at each line and column of the matrix allow deriving the logically correct solution.

The task satisfies several criteria. Subjects can learn the logic of the puzzle within reasonable time. The puzzle can vary in difficulty by increasing or decreasing the size of the matrix. Unlike the famous Sudoku the puzzle is largely unknown. Hence many subjects start from zero[3].

The matrices in the first and second tests are of different size (4x4 and 5x5 respectively). This variation is used to avoid floor or ceiling effects in the learning process. The experiment has been pre-tested with first year university students. Here, the matrices were of identical size in both tests, to show if subjects actually improve. Using 5x5 matrices for puzzles in the first test caused a floor effect. Only few people actually managed to solve a single puzzle. On the other hand, 4x4 matrices for puzzles in the second test are too easy to solve. Many participants did not improve from test 1 to test 2 (a ceiling effect). In the preparation period, the subjects got 4x4, 5x5 and 6x6 puzzles.

2.3 The Procedure

The first experiment was conducted on the 5th of December in 2006 with 85 Swiss students at a public high school (Kantonsschule) in Kreuzlingen in the Canton of Thurgau in Switzerland. A second experiment took place on 26th February, 2007 with 61 students from a similar school in Romanshorn in the same canton. The Canton groups students according to performance into different schools. Both schools roughly capture the top 15% of the students in their hometown.

---

[2]   A detailed description of the puzzle can be found at www.janko.at (in German). The owners of the website created the meaningless name for the puzzle.

[3]   Similar puzzles exist on dedicated homepages on the internet. Hence, it is likely that some participants have an advantage even though they do not know the puzzle.

The students were recruited from the top three grades (age 15-18) through the school's intranet. Students responded via E-Mail and provided information about their grade and sex. Each participant got 20 Swiss Francs (about 12.40 € or 16.25 US$ in December 2006) for their participation. 48 participants were assigned to the single treatment and 96 to the pair treatment group. The subjects were assigned randomly to the different groups. Each subject in the pair treatment group got a randomly assigned partner, but only from the same class level and sex. Due to missing partners three pairs were formed *ad hoc* with subjects from different grades. Table 1 shows the composition of single treatment and pair treatment groups.

All subjects of a school did the experiment at the same time to ensure that students could not communicate solution hints to following students. In Kreuzlingen, the subjects did the experiment in five different rooms in the school. Two rooms were filled with single learners, three rooms with the pair treatment group. The differences across rooms within a specific treatment group are insignificant. In Romanshorn, the students were separated in two different rooms according to their treatment. All the students received their instructions in standardized oral and written form from the author of this paper. Each room contained either 20 or 40 persons. One person per 20 participants was in charge of the technical details (i.e. two persons were in each large room). These supervisors received instructions about the procedure of the experiment but not about the puzzle. The participants were explicitly told that the overseer could not answer questions with respect to the puzzle.

Table 1: The distribution of the subjects into single treatment and pair treatment groups

	Single treatment group			Pair treatment group		
Grade	Male	Female	Sum	Male	Female	Sum
2	11	10	21	27	18	45
3	8	7	15	19	10	29
4	7	6	13	16	6	22
Sum	26	23	49	62	34	96

2.4 Discussion of the Design

The random assignment of subjects into different treatment groups ensures that self selection does not play a role. All subjects face the same problem. Within the pair treatment the groups are of identical size. While verbal interaction between partners was allowed during the preparation period, all subjects faced the same conditions during the tests and the analysis is

based on the results of these tests. As stated above, this is a key difference to Falk and Ichino (2006).

The results of the experiment are likely to change with the task, the subject pool or the pay-out formula. The floor and ceiling effects identified in the pre-tests support this presumption. A change in the result does not imply that the design is inappropriate. The fixed payment keeps the set-up as simple as possible. If financial incentives were the only source of motivation the results in the first test should not differ within and across treatment groups. Since students know each other and cooperate face to face in the preparation period, financial incentives could induce some of them to promise post-experimental rewards or punishments to elicit the desired level of cooperation. Furthermore, the results from Gneezy and Rustichini (2000) show that the impact of financial incentives on performance in tasks with a great cognitive demand is not trivial. Hence, a much larger experimental setup would be necessary which would extend beyond the objectives of this paper. Finally, Deci and Ryan (1985) claim that human beings' "need for competence" is a source of intrinsic motivation equivalent to basic needs for autonomy and social relatedness. This assumption implies that subjects with different marginal productivity will provide different test results. The experiment allows to investigating if it is too simplistic.

The identification of motivational differences between the treatment groups requires that the subjects know about their assignment before the first test. Otherwise no behavioural variable would distinguish between motivational and other aspects of cooperation. The setup does not allow a distinction between different sources of motivation nor exactly quantify the motivational impact. I use econometric analysis to identify possible instructional benefits which are independent of the motivational differences. Using the performance in the first test as a control variable eliminates the impact of motivational differences between the treatment groups. Any resulting difference between the treatment groups derives from the availability of a cooperation partner. Further research with a larger subject pool should address these questions.

3   Results

I present OLS estimations in the subsequent econometric analysis. The performance is measured by counting the number of solved puzzles. Therefore, Poisson regressions or negative binomial regressions seem to be plausible alternatives, depending on the dispersion. The analysis has been conducted with all three methods and differences are reported

whenever they appear. A comparison between the results indicates that OLS regressions are the most conservative method with respect to significance levels for testing the propositions.

Table 2: Descriptive Statistics

	Single Treatment	Pair Treatment
Number of Subjects	49	96
Test 1: Average number of solved puzzles (4x4 puzzles)	3.408 (St.Dev.: 2.806)	4.479 (St.Dev.: 2.546)
Test 2: Average number of solved puzzles (5x5 puzzles)	2,429 (St.Dev.: 1.860)	3.375 (St.Dev.: 1.991)
Math performance in the last year (variable name: *Mathmark*; from 1 (very bad) to 6 (very good))	4.44 (St. Dev.: 0.79)	4.43 (St. Dev.: 0.78)
Share of students with interest in logical puzzles (variable name: *Sudoku*)	65%	80%

A first estimation model shows a difference in the first test between the treatment groups (Table 3). I estimate output on a treatment dummy for the pair treatment (Model 1 in the table). The results show a significant treatment effect even after controlling for heterogeneity between the groups with respect to sex (0 = female, 1 = male), the school grade (*Grade:* 2, 3, or 4) and a school dummy (all in Model 2).[4] Further controls for marks in math and general preferences for logical puzzles support this evidence (Model 3).

---

[4]   No incident of cheating was observed during the test, which could have driven the result. The correlation between the first test score of a subject in the pair treatment and the test score of his prospective partner is .01, which underlines this observation.

Table 3: Estimation of differences between the treatment groups in the first test.

OLS: N=145, dependent variable: *firsttest*; coefficients (robust standard error)			
	Model 1	Model 2	Model 3
Treatment	1.071 (.476)*	1.203* (.477)	1.005* (.461)
Grade		.014 (.266)	.041 (.251)
Sex		.786^ (.445)	.895* (.440)
School		.918* (.428)	.669 (.424)
Mathmark			.639* (.272)
Sudoku			1.527** (.519)
Constant	3.408 (.399)	2.576** (.903)	-1.287 (1.399)
R²	.0361	.0842	.1869
*Significance levels: ***=.001,**=.01,*=.05, ^=0.1*			

There is some evidence about the source of motivation. I estimate the performance in the first with exogenous characteristics of the partner. Any significant characteristic is a source of motivation. In this experiment a partner with a better math score induces lower motivation (Table 4).

Table 4: Estimation of cognitive peer effects in the first test

OLS: N=96, dependent variable: *firsttest*; coefficients (robust standard error)			
Sudokupeer	-1.115 (.559)*		-.849 (.568)
Mathpeer		-.071 (.028)*	-.061 (.028)*
Grade	.233 (.311)	.219 (.314)	.208 (.313)
Sex	1.065 (.512)*	1.304 (.530)*	.1229 (.525)*
School	1.228 (.510)*	1.048 (.499)*	1.161 (.508)*
Constant	3.841 (.985)***	6.120 (1.540)***	6.384 (1.548)***
R²	.1248	.1412	.1577
*Significance levels: ***=.001,**=.01,*=.05, ^=0.1*			

The differences in the second test are also significant. Model 1 in table 5 provides the overall peer effect. However, this significant effect is driven to some extent by the results in the first test (Model 2). The resulting treatment effect is hardly significant on a 10% level. It is insignificant once differences in the group composition are accounted for (Model 3). Model 4

finds a significant treatment effect once a non-linear impact of the first test (*firsttest²*) is taken into account[5].

Table 5: Estimation of differences between the treatment groups in the second test.

OLS: N=145, dependent variable: *secondtest*; coefficients (robust standard error)				
	Model 1	Model 2	Model 3	Model 4
Treatment	.946*** (.334)	.441^ (.263)	.427 (.277)	.519^ (.278)
Firsttest		.472*** (.051)	.468*** (.052)	
Firsttest²				.055*** (.006)
Grade			.155 (.159)	.153 (.154)
Sex			-.156 (.266)	-.212 (.269)
School			.266 (.270)	.339 (.261)
Constant	2.429*** (.265)	.820*** (.222)	.369 (.545)	.892 (.542)
R²	.0508	.4384	.4487	. 4558
*Significance levels: ***=.001, **=.01, *=.05, ^=0.1*				

The final focus is on optimal peer group composition. At first I test for so-called *cognitive* peer effects, i.e. if performance increases in the ability of the partner. The following analysis uses data from the 96 subjects in the peer treatment group. I took several cognitive measures. The score of the partner in the first test (*partnerscore*) does not show any significant effect (Model 1 in Table 6) even as a nonlinear measure[6]. Differences between the schools are interesting. The students in one school perform worse in the first test than their colleagues in the other one, i.e. the task is initially more difficult for them[7]. Estimating the first model in Table 5 separately for each school documents a significant treatment effect in the school with the lower initial performance (p-value = .033) and an insignificant one in the better school.

Other independent predictors have been taken from the questionnaires, e.g. the partner's math grade in school (*mathpeer*) or his interest in logical puzzles (*sudokupeer*). The partner's interest in logical puzzle has a significant effect (Model 2) but it reduces once it is controlled for the math mark (p-value: .100). The partner's performance in math is always an insignificant contributor to the performance of a subject. No differences across the different subgroups are observable. The final questionnaire included questions about the quality of

---

[5] The p-value for the treatment effect is .093 if model 4 is estimated with both *firsttest* and *firsttest²*.

[6] Even if it was significant, it would be affected by Manski's (1993) reflection problem.

[7] The p-value in a two-sample t test is .0438.

cooperation, how subjects liked their partner, if they were in the same class etc. None of these variables has a significant impact. Overall, the results do not allow any definite conclusion about the dominance of any particular group composition policy. Further research with a larger subject pool is required.

Table 6: Estimation of cognitive peer effects in the second test

OLS: N=96, dependent variable: *secondtest*; coefficients (robust standard error)

4   Summary and Discussion

The experiment introduced in this paper confirmed the benefits from cooperation in a learning context with an experiment and allowed some insight into the mechanisms of peer interaction. The experimental approach circumvents key econometric problems which greatly restrict the analysis of peer interaction with administrative or survey data. The results show that prospective cooperation has a motivational effect which induces a learning benefit. The benefit from cooperation shows no robust relationships with the characteristics of the partner. Partners with an interest in logical puzzles improve test performance in the second test. On the other hand subjects with a high math score reduce the motivation of their partner.

The results have some clear implications. Peers matter in learning processes. In particular, they induce higher motivation. This motivation decreases in the ability of the partner. Further research is required to identify how peers induce motivation. The paper also contributes to the understanding of peer effects in general. Peers have an impact on performance not just during interaction but also before and afterwards.

The results do not imply that cognitive or other aspects of peer interaction are irrelevant. A simple variation of the experiment – and an increased subject pool - could provide more robust outcomes in that area. A brief discussion should suffice to sketch possible variations of the experiment to achieve this. The actual treatment starts 25 minutes after the experiment has begun. Reducing this time decreases the performance in the first test and enhances the relative importance of the treatment period for the success in the second test. Increasing the complexity of the task (e.g. by changing the puzzles in the first test to a 5x5 matrix) can have a similar effect because it takes longer to "digest" the logic behind the puzzle. The reported differences between the schools support this consideration. Variations in the timing may also provide some evidence about the optimal composition of learning groups.

The econometric literature has investigated peer effects in schools in various ways and with different conclusions[8]. However, motivational aspects have largely been ignored. The results of this paper indicate to the very least that the consideration of motivation in future research will provide a better understanding of interaction among students.

---

[8]   Take for example, Table 1 in Ammermüller and Pischke (2006)

Appendix A: Introductory letter

The participants in the different treatment groups received different introductory letters. The appendix merges both letters. The participants did not know anything about the treatment in the other group. The letter is translated from German.

Dear participant,

You take part in an research project about the learning of logical puzzles. The experiment will go on for about one hour. Thank you very much for your participation.

We will test you twice in the experiment, at the beginning and at the end. In both tests we investigate, how many puzzles you can solve within a specific time.

Instruction for single treatment group:

> **Please put your solution for each puzzle in the solution sheet only.**

Between both tests you have twenty minutes to learn more about the logic of the puzzle. You get a sheet with more puzzles to do so.

> **Please work alone during the entire experiment.**

Instruction for pair treatment group:

> **Please solve these tests alone.**
>
> **Please put your solution for each puzzle in the solution sheet only.**

Between both tests you have twenty minutes to learn more about the logic of the puzzle. You get a sheet with more puzzles to do so. In **this** period you can cooperate with another participant. The seat number of your partner is on the sheet with your own number.

Instruction for both groups:

We ask you to answer two questionnaires, one at the beginning and one at the end of the experiment. We ensure the anonymity of the results. You will get 20 Francs once you hand in the last questionnaire at the end.

You will find the rules for the puzzle on the next sheet. Please read them carefully. We cannot answer any questions in order to keep the conditions identical for all participants. Please do not worry if you do not understand the rules immediately. It is neither uncommon nor embarrassing.

Yours sincerely.

Appendix B: Rules (Translated from German)

> **Your task in the test: Solve as many puzzles as possible by marking the correct boxes in the puzzle.**

The composition of a puzzle:

We can explain it with the help of the following example:

```
         5   6   1   2
      ┌───┬───┬───┬───┐
   3  │   │   │   │   │  1
      ├───┼───┼───┼───┤
   7  │   │   │   │   │  2
      ├───┼───┼───┼───┤
   1  │   │   │   │   │  3
      ├───┼───┼───┼───┤
   2  │   │   │   │   │  4
      └───┴───┴───┴───┘
        1   2   3   4
```
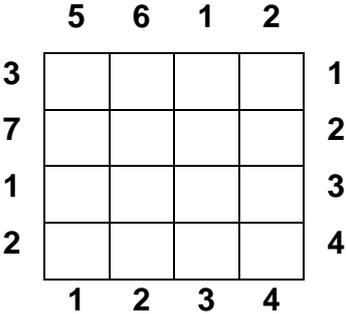

The puzzle is surrounded by numbers. These are very important. The numbers at right boundary and at lower boundary assign values to the different boxes.

> **Please bear in mind:**
>
> **Each box has two different values!**

1. At the right boundary you find the values for each box in the respective row.

	5	6	1	2	
3	1	1	1	1	**1**
7	2	2	2	2	**2**
1	3	3	3	3	**3**
2	4	4	4	4	**4**
	1	**2**	**3**	**4**	

All boxes in row one have value 1.

All boxes in row two have value 2.

All boxes in row three have value 3.

All boxes in row four have value 4.

2. At the lower boundary you find the values for each box in the respective column.

	5	6	1	2	
3	1	2	3	4	**1**
7	1	2	3	4	**2**
1	1	2	3	4	**3**
2	1	2	3	4	**4**
	1	**2**	**3**	**4**	

All boxes in the first column have value 1

All boxes in the second column have value 2

All boxes in the third column have value 3

All boxes in the fourth column have value 4

Here you find the values for each box again. (row value / column value).

	5	6	1	2	
3	1 / 1	1 / 2	1 / 3	1 / 4	**1**	← All boxes in row one have value 1.
7	2 / 1	2 / 2	2 / 3	2 / 4	**2**	← All boxes in row two have value 2.
1	3 / 1	3 / 2	3 / 3	3 / 4	**3**	← All boxes in row three have value 3
2	4 / 1	4 / 2	4 / 3	4 / 4	**4**	← All boxes in row four have value 4.
	1	**2**	**3**	**4**	

All boxes in the first column have value 1.

All boxes in the second column have value 2.

All boxes in the third column have value 3

All boxes in the fourth column have value 4.

16

3. The numbers at the *left* boundary show the sum of the values of all marked boxes in the respective *row*.

In this case, the values at the *lower* boundary are the relevant values.

The sum in row one is 3

The sum in row two is 7

The sum in row three is 1

The sum in row four is 2

	5	6	1	2	
3					1
7					2
1					3
2					4
	1	2	3	4	

4. The numbers at the *top* boundary show the sum of the values of all marked boxes in the respective *column*.

In this case, the values at the *right* boundary are the relevant values.

The sum in column one is 5

The sum in column two is 5

The sum in column three is 1

The sum in column four is 2

	5	6	1	2	
3					1
7					2
1					3
2					4
	1	2	3	4	

> **Now you have to mark the boxes, ensuring that both the values on the top and at the left boundary are correct.**

Our example has the following solution

```
         5   6   1   2
     3 ┌───┬───┬───┬───┐ 1
       │   │   │ X │   │
     7 ├───┼───┼───┼───┤ 2
       │ X │ X │   │ X │
     1 ├───┼───┼───┼───┤ 3
       │ X │   │   │   │
     2 ├───┼───┼───┼───┤ 4
       │   │ X │   │   │
       └───┴───┴───┴───┘
         1   2   3   4
```

Is the solution correct?

In *row one,* the sum of all marked boxes has to be 3. Only the third box is marked, its value is 3 (see lower boundary). Hence, the solution in this row is correct.

In *column one*, the sum of all marked boxes has to be 5. The second and the third box are marked: 2+3=5 (see right boundary). The solution in this column is correct.

Indeed, the marked boxes ensure a correct solution for the values on the top and the left.

Row one: $3 = 3$ Column one: $5 = 2+3$

Row two: $7 = 1+2+4$ Column two: $6 = 2+4$

Row three: $1 = 1$ Column three: $1 = 1$

Row four: $2 = 2$ Column four: $2 = 2$

For the sums in each **row**, take the marked boxes in this row with the corresponding values at the **bottom**.	For the sums in each **column**, take the marked boxes in this column with the corresponding values at the **right**.

If you do not understand the solution at the moment, it is no problem. Go through the solution once. Or maybe the following test can help you. Good luck.

Appendix C: The Questionnaires (translations from German)

Questions in the first questionnaire:

- Sex (Boxes: male and female)
- How old are you?
- What are your preferred subjects in school? Note up to three
- What are your three best subjects in school?
- What was your math mark in last year's final certificate?
- What was your overall average mark in last year's final certificate?
- Do you like to go to school? (Boxes: yes and no)
- Do you often prepare for exams with other students? (Boxes: yes and no)
- Can you explain difficult topics successfully to others (e.g. solution for difficult mathematical tasks)? (Boxes: yes and no)
- Do you get along with most of your fellow students? (Boxes: yes and no)
- Do you like to solve logical puzzles, e.g. Sudoku? (Boxes: yes and no)
- Are you member in a club? (Boxes: yes and no)
- If yes, what type of club is it?

Questions ahead of each test

- Do you understand the rules of the puzzle? (Boxes: yes and no)
- What do you expect? Will you solve the puzzles easily or with difficulty? (5 Boxes, very easy to very difficult)
- Will your performance in this test be above or below the average performance of the other participants? (5 Boxes, much below average to much above average)

Questions in the final questionnaire:

- Compared with your expectations, did you find the puzzles easier or more difficult to solve. (5 Boxes, much easier to much more difficult)
- Do you expect to perform better than the average? (5 Boxes, much worse to much better)
- How was the quality of cooperation with the partner? (5 Boxes, very good to very bad)

- Was your partner helpful during the preparation? (5 Boxes, very helpful to not helpful at all)

- Did you know your partner before the experiment? (Boxes: yes and no)

- Are you in the same grade? (Boxes: yes and no)

- Are you in the same class? (Boxes: yes and no)

- Does your partner live in your vicinity? (Boxes: yes and no)

- Do you prepare occasionally with him for classes or exams? (Boxes: yes and no)

- How much do you like your partner ? (5 Boxes, very much to not at all)

- Did you like the experiment? (Boxes: yes and no)

- Are you interested in the results of the experiment? (Boxes: yes and no)

- Do you want to participate in similar experiments in the future? (Boxes: yes and no)
